## A Brief Statement Regarding the Most Innovative Contribution:

Interaction between heme centers has been smartly implemented by Nature to regulate a wide variety of functions of the *multiheme proteins and enzymes*. Rath's group is pioneer in the structure-activity correlation study of this new class of proteins and contributed significantly to unfold mysteries of Nature's sophisticated design for sustainable development and applications.

## Highlights of the Major Scientific Contributions

The family of *multiheme proteins and enzymes* constitutes one of the most fascinating molecular machineries designed by Nature to execute a large variety of functions which awaits an eventual blossom for its potential application towards sustainable development. Recent discoveries of newer proteins in large numbers and their involvement in various biological processes have raised two immediate questions: what are the selective advantages of containing so many redox co-factors in a single polypeptide chain, and why did the spatial distribution of the co-factors evolve to be the way it is? However, the presence of large number of heme centers and efficient coupling between them hinder detailed analysis. Although, mono heme protein/enzyme and their model compounds have already been studied extensively, however, only a few in vivo studies are reported with multiheme. Interaction between heme centers has been smartly implemented to perform a wide variety of functions in

biology. Rath's group is pioneer

in the world to unfold mysteries of Nature's sophisticated design and implementation of the knowledge for our sustainable future developments. The investigation also highlights excellent

cooperativity between various biological units of enzyme for its extraordinary functions. Such investigations have also paved the way for new important discoveries that includes unusual stabilization of high-valent  $M(IV)=O$  species, easy modulation of spin and oxidation states, heme-heme interactions as a powerful tool for controlling electronic structure and reactivity, highly efficient biocatalyst for sustainable development, hitherto unknown metallophilic  $Ag(III)\cdots Ag(III)$  interaction and so on.

Rath's group has recently reported the first-ever unusually stable synthetic *bis*- $Fe(IV)=O$  intermediate that closely mimics similar intermediate generated in the catalytic cycle of the native diheme enzymes and display similar stability at room temperature and, thereby, shedding light into the unexplored world of diheme enzymes.

**Supramolecular chirogenesis** is one of the most important interdisciplinary fields of science today and is directly relevant to the functioning of living organisms and many aspects of human life. Rath's group has been at the forefront in understanding the origin and underpinning mechanism of chirality induction and control at the molecular level using multi-metallporphyrin helices.
